REGISTRATION LONDON.

- Area.—The Area of Registration London is 78,052 acres or 122 square miles, including 2718 acres of tidal water; this is equal to 31,585 hectares, or 316 square kilometers. The length of the streets and roads is more than 1600 miles. The Area of London being 122 square miles is equal to a square of about 11 miles to the side.
- ELEVATION.—The population of London resides at a mean elevation of 39 feet (11.9 metres) above Trinity high-water mark; the elevation varying from 11 feet (3.4 metres) below high-water mark in Plumstead Marshes, to 429 feet (131 metres) above high-water mark in Hampstead.
- Houses.—At the Census in 1881 there were within this area 486,186 inhabited houses, containing an average of 7.8 persons to a house, exactly corresponding with the proportion in 1861 and in 1871.
- Annual Rateable Value.— The Annual Rateable Value of Property in the Metropolis, in April 1881, as assessed in accordance with the Valuation (Metropolis) Act, 1869, was £27,402,509.* (For Annual Rateable Value of Greater London, see Table 8.)
- Density (1885).—134 persons to a hectare; 54·2 persons to an acre; 34,695 to a square mile. (These are calculated exclusive of tidal water.)
- Annual Rate of Increase of Population per cent. $\begin{cases} 1861-71. & 1.50\\ 1871-81. & 1.61 \end{cases}$

^{*} This amount represents the Annual Rateable Value of Property within the District of the Metropolitan Board of Works, as defined by the Metropolis Local Management Act, 1855 (18 & 19 Vict. c. 120.) The District of the Metropolitan Board of Works is identical with that adopted for Poor Law and Registration purposes, except that the hamlet of Penge, in Croydon District, is situated within the District of the Metropolitan Board of Works, but is excluded from Registration London; and the hamlet of Mottingham, in Lewisham District, is included with Registration London, but excluded from the District of the Metropolitan Board.

ANNUAL SUMMARY.

LONDON,

AND OTHER GREAT TOWNS,

1885.

General Register Office, Somerset House, 27th February, 1886.

The Great Towns.

The twenty-eight great towns of England and Wales that have a place in the Weekly Returns contained an estimated population of 8,906,446 persons in the middle of 1885. The deaths recorded among this population in the course of the year numbered 182,339, and were in the proportion of 20.5 per 1000 living. In each of the two immediately preceding years, 1883 and 1884, the rate had been 21.6, and in 1882 had been 22.3 (see Table 2).

The rates varied very greatly in the different towns, and ranged from 17·1 in Brighton and 17·2 in Hull, to 26·1 in Newcastle-upon-Tyne, 26·5 in Manchester, and 27·1 in Preston. Owing, however, to the great differences between one town and another, in regard to the age and sex distribution of their respective populations, these recorded death-rates require correction before they can justly be used for purposes of comparison; and factors were given in the Annual Summary for 1883, by which such necessary correction can be made with approximate accuracy. Applying these factors we have the corrected rates, which are given in the second column of the following Table. In the third column the death-rate for all England and Wales (19·00) has been taken as 1000, and the corrected death-rate in each town has been reduced to a figure comparable with that standard. That third column may be read as follows:—After making due correction for differences of age and sex distribution, the same number of living persons that gave 1,000 deaths in England and Wales gave 926 deaths in Brighton, 933 deaths in Hull, &c. &c., and 1553 deaths in Manchester.

Particulars of the registered mortality in the several Great Towns, and especially of the mortality from the chief zymotic diseases, are given in Tables 1 to 4. The highest death-rates from *small-pox* were in London and Sunderland; from *measles* in Cardiff, Newcastle-upon-Tyne, and Sunderland; from *scarlet fever* in Preston, Leieester, and Sunderland; from *diphtheria* in Portsmouth and Cardiff; from *whooping-cough* in Plymouth, Cardiff, and Blackburn; from *fever* in Portsmouth and Norwich; and from *diarrhæa* in Salford, Leicester, and Preston. The highest death-rates from these seven causes in the aggregate were in Preston, Newcastle-upon-Tyne, Cardiff, and Sunderland.

In fifty other Town Districts (Table 5.) which, though not so large as the twenty-eight Great Towns, are yet of considerable size, and contain in the aggregate a population of nearly 3 millions, the death-rate in the year was 19.6 per 1000, and therefore not very much above the rate (19.0) for all England and Wales. The recorded death-rates ranged in these Town Districts from 13.8 in Barrow-in-Furness, and

in Burton-on-Trent, and 15:2 in Hastings, to 23:5 in Wigan, 24:3 in Merthyr Tydfil, and 24:6 in Stockport.

The infantile death-rate, or proportion of deaths of infants in the first year of life to 1000 registered births, was 138 in England and Wales; 150 in the fifty Large Town Districts, and 155 in the twenty-eight Great Towns. The proportion, however, reached 189 in Cardiff, 193 in Leicester, and 218 in Preston.

London.

The year 1885 was remarkable from a statistical point of view; for the marriagerate and the death-rate in London were the lowest on record, and the birth-rate the lowest since 1850.

MARRIAGES.

The marriages celebrated in London in 1885 numbered 34,573, giving a proportion of 16.9 persons married to 1000 inhabitants. This was the lowest marriagerate as yet recorded in London; and the two next lowest, moreover, were those of the two immediately preceding years 1883 and 1884, when the rates were 17.9 and 17.6 respectively.

BIRTHS.

The births registered in London in 1885 (52 weeks) numbered 132,506, and corresponded to an annual rate of 32.6 per 1000 inhabitants. This was the lowest rate on record since 1850, when the rate was 32.0. The excess of births over deaths, or natural increment of the population, was 52,506, or about 1000 a week, a rate of natural growth which was pretty nearly the same as that of the five preceding consecutive years.

DEATHS.

The deaths registered in the year (52 weeks) were exactly 80,000, and corresponded to an annual rate of 19.7 per 1000 inhabitants. This was the lowest rate on record in London; the two next lowest, moreover, having been those recorded in the two immediately preceding years 1883 and 1884, when the death-rates were 20.5 and 20.4 respectively.

As in 1883 and 1884, so also in 1885, some small share in producing the low death-rate is attributable to the low birth-rate. Had the birth-rate been equal to the average in the preceding decennium (1875–1884), 10,431 more infants would have been born in the year; and, with an infantile death-rate of 148 per 1000 (Table 4.), there would have been 1544 additional infant deaths, which would have raised the general death-rate from 19·7 to 20·0 per 1000, which rate would still have remained the lowest on record.

Had the deaths in London in 1885 equalled the corrected average annual number in the preceding decennium (Table 15), 8412 persons would have died in the year, who, as it was, were alive at its close.

The following Table, which is based on the figures given in Table 15, shows in a summary form the amount of life saved and the amount lost in the year, compared with the mean annual mortality in the previous decennium, under the more important headings in the list of causes.

DIMINUTION OF EXCESS of DEATHS in 1885, compared with Annual Deaths in 1875-84, corrected for increase of Population.

^{*} Table 15 shows a diminution of 139 deaths from small-pox; but that Table includes only the deaths registered in London, whereas in the above table the deaths of London residents from small-pox that occurred in the Metropolitan Asylum Hospitals outside Registration London in 1884 and 1885 have been taken into account. This same explanation applies to the figure showing the total saving of life; the balance of saved lives according to Table 15 is 8412, whereas with the additional small-pox deaths the saving is reduced to 7908.

If the foregoing Table be compared with the corresponding Tables in the Annual Summaries for 1883 and 1884, it will be seen that there is a very general agreement between the three as regards the headings which show respectively excess and diminution of mortality.

Thus there is an excess in 1885 under measles, diphtheria and croup, cancer, premature birth, diseases of the circulatory system, and diseases of the urinary organs, and each of these headings also showed excess in 1883 and 1884. On the other hand there is a diminution in 1885 under scarlet fever, typhus, enteric fever, simple continued fever, erysipelas, phthisis, diseases of the nervous system, diseases of the respiratory organs, murder and accident; and there was also diminution under each of these headings in each of the two preceding years.

Under the remaining headings there has not been a similar persistency of change. Diarrhœa, dependent mainly on temperature, showed excess in the hot summer of 1884, but was under the average in the cooler summers of both 1883 and 1885.

Small-pox mortality was below the decennial mean in 1883, but both in 1884 and 1885 was in considerable excess, owing to an outbreak that commenced (Table 24) towards the end of the first quarter of 1884 and lasted to the middle of the third quarter of 1885, or for a period of eighteen months, the beginning and the end of

the outbreak being taken to be the weeks in which the number of registered deaths from this cause exceeded ten for the first and last times respectively. In 351 of the 899 fatal cases in the year 1885 no adequate information was furnished as to whether the deceased had been vaccinated or not. Of the remainder 218 had, and 330 had not, been vaccinated; so that, assuming the ordinarily accepted estimate to be correct that only about five per cent. of the population are unvaccinated, the deaths from small-pox of the unvaccinated would be to the deaths of the vaccinated, out of equal numbers living, as 29 to one.

The mortality from whooping-cough showed a considerable falling off in 1885 as it had also done in 1883, whereas in 1884 it had equalled the average. Some part in the diminished mortality from this disease is probably attributable to the low birth-rates of recent years, owing to which the proportion of infants and young children in the population has undergone reduction.

Under the heading alcoholism there was a diminution of 50 deaths, which is the more satisfactory as there had been an increased mortality from this cause in the two preceding years. Probably in connexion with this decline in fatal intemperance was the decline under suicide, which also had shown excess in 1883 and 1884.

Much alarm was felt in the year by the numerous cases of hydrophobia, and this led to energetic measures on the part of the police in regard to stray dogs. The deaths ascribed to this disease in the year were 27, and not only much in excess of the average, but more numerous than in any previous year; the nearest approach having been in 1877, when 16 deaths from this cause were registered.

Under childbirth and puerperal fever there is in the Table a saving in 1885 of 64 lives; but this apparent saving was in reality due to the low birth-rate. If the deaths from these causes be compared with the births, the childbirth mortality was very nearly the same as in recent years, being in the proportion of 3.8 deaths to 1,000 live births.

Of the diseases mentioned above as having shown a persistent decline for some years, there is one, namely scarlet fever, that deserves special attention. Although a huge town, such as London, apparently supplies all the requisite conditions for the propagation of infectious diseases, and although whooping-cough and measles do, in fact, witness to the presence of such conditions by their almost constant excess, yet for some reason or other the mortality from scarlet fever has for years been lower in London than in the country at large. This was the case in the decennium 1871-80, and also in the first half of the present decennium. On the other hand in the previous decennium 1861-70, no such comparative freedom from scarlet fever was observable; on the contrary, the mortality from this disease was higher in London than in the whole country. It may be suggested as a not impossible explanation of this curious change in the relation of scarlet fever to London, that the decline in mortality may be due to the increasing use of public hospitals for cases of this disease, in other words, to improved isolation. increased use of hospitals is readily shown by calculating the proportion, of all deaths from scarlet fever, that occur in the Metropolitan Asylum Hospitals. In 1878 the proportion was 5 per cent.; in the next three years, 1879-81, it was from 7 to 8 per cent.; in 1882 the percentage rose to 9.3, in 1883 to 11.4, in 1884 to 16.4 and finally in 1885 to 19.2. This suggestion as to the possible cause of the recent persistently low mortality from scarlet fever in London is, at any rate, one that deserves attention and examination by those engaged in sanitary administration.

The deaths caused by accident in 1885 numbered 2,303, and, after due correction for growth of population, were 425, or 15.6 per cent., below the annual average of the 10 preceding years. The largest saving was in deaths from drowning, which were fewer in 1885 than in any one of the 10 preceding years (Table 16), and fell from an average of 423, or, excluding the year 1878 when the "Princess Alice" accident raised the number to an exceptional figure, from an average of 365 to 233. There was also a not inconsiderable decline in the deaths from suffocation, the bulk of which are deaths of children overlaid by their mothers. These fell from an average of 650 to 574, a decline of 12 per cent.

Among the 2,303 accidental deaths were 266 caused by horses and conveyances in the streets, the number having been almost exactly the same in 1884.

The following Table shows the shares taken in the mortality by different kinds of vehicles, and it will be observed that the increase in the number of fatal accidents from cabs, which was noted in 1883 and 1884, was maintained in 1885. There was also a considerable excess in the accidents caused by private carriages, while on the other hand the accidents caused by omnibuses and tramcars showed considerable reduction.

Mortality in different parts of London.—The registered mortality was as usual very unevenly divided between the different parts of London; but it will be seen on referring to Table 13 that in each one of the five great groups of districts the mortality in the year was the lowest on record since 1850. For fair comparison, however, of one group of districts with another, it is necessary to make very considerable correction for the presence in some parts of general hospitals, that admit patients from outside their own areas. In order, then, to enable medical officers of health to carry out the necessary corrections in their own sanitary districts, the following Table has been constructed, in which the hospital deaths have been transferred to the districts from which the patients were admitted, and certain other corrections made as explained in the note to the Table.

and the second to the second remaining the flow mentaged in contrary administration.

Note.—In the above Table the deaths in Hospitals and in other Public Institutions have been distributed to the sanitary areas from which the deceased impates were admitted. The deaths of 504 London residents who died from small-pox in the Metropolitan Asylum Hospitals outside Registration London have been included and similarly distributed; while, on the other hand, the deaths of 1,063 non-residents who died in Public Institutions inside London have been excluded.

If the figures in this Table be taken as the basis, and the rates calculated afresh for the five great groups of districts we have corrected rates as follow:—

| West Districts | 3.4 | uff 9/5 全日 | 17.7 | per 1000 |
|-------------------|--------|------------|------|----------|
| North Districts | D.582 | 200002 | 18.5 | 19 m |
| Central Districts | | THE PERSON | 25.5 | 27 |
| East Districts | 10 003 | THE PERSON | 22.1 | 99 |
| South Districts | 1 | PRO SER | 18.8 | 21 |

It will be seen, on comparing these figures with those given in Table 13, that, in the absence of due correction, the death-rate in the West Districts is considerably over-stated, and the death-rate in the Central Districts very considerably understated; while the changes in the other three groups are comparatively insignificant.

Uncertified Deaths.—In 908 cases, or 1·1 per cent. of the deaths registered, the cause of death was not certified either by a registered medical practitioner or by a coroner; in the two preceding years the proportions of uncertified deaths were 1·2 and 1·3 per cent., respectively. The proportions of uncertified causes of death in the twenty-seven provincial towns ranged from 0·6 in Plymouth, 1·2 in Brighton, and 1·3 in Portsmouth, to 4·8 in Liverpool, 5·6 in Hull, 6·1 in Sheffield, 7·0 in Halifax, and 7·5 in Oldham.

GREATER LONDON.—The population of Greater London (Table 7), which is co-extensive with the Metropolitan and City Police Districts, was estimated at 5.199.166 persons in the middle of 1885. The death-rate in this population was 19.2 per 1000 in 1885, against 19.7 in each of the two preceding years. In Inner or Registration London the rate was, as we have seen, 19.7, whereas in the Outer Ring of suburban districts, having an estimated population of more than a million persons, it did not exceed 17.5, and corresponded with the rate in the preceding year. The death-rate from the principal zymotic diseases was 2.78 per 1000 in Greater London, against 2.58 and 3.20 in the two previous years. In Inner London and the Outer Ring the zymotic rates in 1885 were 2.77 and 2.82 per 1000 respectively. It is noticeable that the death-rates from small-pox, diphtheria, and fever, in the Outer Ring in 1885, considerably exceeded those from the same diseases in Inner, or Registration London. The rate of infant mortality, measured by the proportion of deaths under one year to registered births, was 143 per 1000 in Greater London, against 152 in the preceding year; in Inner London the rate was 148, whereas in the Outer Ring of suburban districts it did not exceed 127, showing a considerable decline from the rate in the previous year.

HEALTH OF FOREIGN CITIES.—The rate of mortality in twenty-nine Foreign cities (Table 6) averaged 25.8 per 1000 of their estimated population in 1885. In the three principal Indian cities the mean rate was 30.7; the rate was 28.2 in Bombay, 28.9 in Calcutta, and 37.4 in Madras. Small-pox caused 156 deaths in Calcutta, 71 in Bombay, and 24 in Madras; 411 fatal cases of measles occurred in Bombay. The deaths attributed to diarrhoal diseases, including cholera, were 1562 in Bombay, 1604 in Calcutta, and 2804 in Madras. In twenty-two of the largest European cities, having an estimated population of above ten millions of persons, the mean rate of mortality was 25.7 per 1000, which exceeded by 5.7 the mean rate in the twenty-eight great English towns dealt with in this return. The lowest death-rates in these European cities were 20.4 in Copenhagen, 20.7 in Geneva, 21.1 in Christiania, and 21.6 in Brussels; the rates in the other towns ranged upwards to 29.4 in St. Petersburg and Buda-Pesth, 29.8 in Venice, 30.0 in Breslau, 30.3 in Trieste, and 32.0 in Prague. The rate of mortality in Paris, was 23.5, against rates ranging between 28.6 and 25.5 in the four preceding years; it exceeded the rate in London by 3.8. The deaths in Paris included 3957 from diarrheal diseases, 1647 from diphtheria and croup, 1498 from measles, and 1302 from typhoid fever; the fatal cases of typhoid fever showed a further considerable decline from the high numbers returned in recent years. In Berlin, the third European city as regards population, the rate of mortality was 24.6, showing a further decline from 29.0 and 26.4 in 1883 and 1884; the deaths last year included 4394 from diarrheal diseases, and 1817 from diphtheria. Small-pox caused 868 deaths in Vienna, 327 in Venice, 241 in Trieste, 230 in Rome, 181 in Buda-Pesth. and 175 in Paris. Diphtheria, again in 1885, showed considerable mortality in most of the German and Austrian cities, especially in Trieste, Dresden, Hamburg, and Berlin. In four of the largest American cities the mean recorded death-rate was 23.7, and slightly higher than the rate in 1884; in the several cities the rate was 19.8 in Baltimore, 22.0 in Philadelphia, 23.2 in Brooklyn, and 26.2 in New York. Diphtheria showed fatal prevalence in New York, Brooklyn, and Philadelphia; and 594 deaths from typhoid fever were reported in Philadelphia.

Note.—The letter M or P affixed to the name of each Town denotes whether the limits, which the District or Sub-districts named in the last column approximately represent, are Municipal or Parliamentary. Impt. D. signifies an Improvement District.

These estimates, excepting those for Barrow-in-Furness and Ystradyfodwg, are based upon the numbers enumerated at the Census in 1881, and raised to the middle of 1885 by the addition of 4½ times the annual rate of increase that prevailed between 1871 and 1881. The populations of Barrow-in-Furness and Ystradyfodwg have been estimated from special returns of inhabited houses furnished by the local authorities. I The rates of mortality for these towns have been corrected by the exclusion of a proportional number of deaths occurring in County Hospitals and Lunatic Asylums, situate within the District or Sub-districts here taken as representing the towns, or by the exclusion or addition of a proportion of the deaths in Union Workhouses in cases where only a portion of the Union is embraced by the axelusion or where the Workhouse is situated outside that area.

| Diseases of Circulatory System | 5280 | 5755 | 48 | 35 | • 447 | 907 | 1824 | 2214 | 280 |

^{*} These averages have been raised for increase of population between the middle of the period 1875-94, and the middle of 1885, and also to afford comparison with the deaths recorded in the 52 weeks of 1885. For the population at each group of ages, estimated to the middle of 1885, see Table 52.

† Those cases of small-pox only are returned as "Vaccinated" or as "Unvaccinated" which are so certified by registered medical men. When the medical attendant does not certify that the deceased has, or has not, been vaccinated, or when the cause of death is not certified by a registered practitioner, the case is returned under the heading "No Statement."

In consequence of changes of classification the deaths from these diseases in years prior to 1832 cannot be ascertained; the averages are therefore only for the three years 1882-84.

Table 15 (continued).—Deaths Registered in London at several groups of Ages from different Causes during the 52 Weeks ending Saturday 2nd January 1886.

^{*} Sec note * on preceding page. † The evidence at inquests is often insufficient to enable the coroner to certify whether a violent death resulted from accident, nurvler, manslaughter, or suicide. All such cases are classed under accident or negligence." † In consequence of changes of classification the deaths from these diseases in years prior to 1882 cannot be ascertained, the averages in these cases are therefore only for the three years 1882-84.

Table 16.—Causes of Deaths Registered in London in each of the 11 Years 1875-1885, and in each Quarter of 1885.

Note. — This Table is compiled from the Abstracts which appear in the Registrar General's Annual Reports, excepting for the year 1885, for which the numbers are derived from the Weekly Returns embracing 52 weeks.

^{*} These areas have been supplied to the Registrar General by the Ordnance Survey Department, and include 2718 acres of tidal water, or of the river Thames. For area of Greater London see Table 8.

[†] Prior to 1st January 1885, Paddington and Kensington constituted one Registration District.

BLE 18.—LONDON.—Births and Deaths; Deaths of Infants under 1 Year of Age, and of Persons aged 60 Years and upwards, from ALL CAUSES; DEATHS from the principal ZYMOTIC DISEASES and from VIOLENCE; INQUEST CASES, DEATHS in Public Institutions, and Uncertified Deaths, in Groups of DISTRICTS, and in each REGISTRATION DISTRICT during the 52 Weeks ending Saturday, 2nd January 1886.

Note.—This Table does not include the deaths in Wandsworth and Clapham for the years 1841-3; nor the deaths in Hampsteal and Lewisham for 1841-6.

(a) The deaths in this Table as well as the Meteorology are compiled from the Registrar General's Weekly Returns, which embrace 344 days (for eight years 1847, 1853, 1857, 1863, 1879, and 1884, 371 days); for this reason the figures differ from those which relate to complete years from 1st January to 31st December, published in Table 17.

*The column headed "Dryness of Atmosphere" shows the difference between the dew point temperature and air temperature. The mean dew point temperature, for any year, may be obtained by subtracting the number in the column headed "dryness" from the mean temperature in the same period.

† For the years 1850-59 the results are only approximative, having been reduced to Robinson's anemometer from observations made with Whevell's.

‡ Average of 30 years.

^{*} The column headed "Dryness of Atmosphere" is the difference between the dew point temperature and air temperature. The mean dew point temperature, for any week, may be obtained by subtracting the number in the column headed "dryness" from the mean temperature in the same period. † By Robinson's Anemometer, adopted in place of Whewell's, which was used formerly.

^{*} A cubic metre is equal in volume to 35 3 cubic feet, or to 220 09668 imperial gallons. It is nearly equivalent to the old English tun of four hogsheads, holding 35 248 cubic feet. It is in general use on the Continent; and its volume of water weights a metric ton, differing inconsiderably in weight from the ton in common use. It is equal to 100 decalitres: thus a decalitre equals 2 2009668 gallons.

[†] According to returns of the London Water Companies made to the Select Committee on East London Water Bills (Session 1867), it is estimated that during the year 1866 about \$2 per cent. of the total supply of water for all purposes was for domestic use; this proportion has been applied in estimating the quantities for the year 1885 in columns 4, 5, and 6, showing the gallons probably used for domestic purposes. The average daily quantity of water supplied by the London Companies during the year 1885 was 154,823,419 gallons (703,434 cubic metres, equal to about as many tuns by measure, tons by weight), of which about 126,955,204 gallons (576,816 cubic metres) were probably used for domestic purposes. The average quantity used daily for domestic purposes in each house (see Col. 6) is equal to \$3 °0 decalitres, and corresponds to 23 °4 gallons (10 °6 decalitres) to each person. The Returns of the Water Companies include uninhabited houses.

REPORT on the Analysis of the Waters supplied by the Metropolitan Water Companies during the several Months of the Year 1885. By Professor Frankland, D.C.L., F.R.S., &c.

Grove House, Pembridge Square, W., 16th February 1886.

I HAVE to report to you upon the results of my monthly chemical examinations of the water which was supplied to the inner, and portions also of the outer, circle of the Metropolis during the year 1885.

SIR.

The general meteorological conditions during the past year resembled, on the whole, those of the previous one, the summer being again exceedingly dry. In consequence of the long drought, much difficulty was in many places, but fortunately not in London, experienced in obtaining an adequate supply of water. The absence of heavy floods in the basins of the rivers Thames and Lea, from which the Metropolitan water-supply is mainly derived, secured for the waters of these streams an exceptional freedom from organic matter during a large portion of the year. With the return of autumn, however, a heavy rainfall took place, and the floods were, as usual, accompanied by a large increase in the amount of organic matter. Notwithstanding, however, the unusually bad state of the rivers in November and December, as indicated by the proportion of organic matter being greater than in any month during the last three years, the water supplied by the Companies was, almost without exception, clear and free from any turbidity. This strikingly illustrates the very great improvement in the equipment of the Companies, by which they are now able to deal very much more efficiently than formerly with these periodical flood waters. To this subject, however, I shall have occasion to refer again in the course of this report.

During the past year the inner circle of the Metropolis has been supplied with an average daily volume of water estimated at 154,823,360 gallons. This amount is in excess of the average daily supply in 1884 by two and a half millions of gallons, whilst the average consumption of water per head of population suffered a slight diminution, being 29.0 gallons per day in 1884 and 28.6 gallons in 1885. Of the total volume, as much as 79,105,021 gallons were, on an average, taken from the Thames, 64,817,635 gallons from the Lea, and 10,900,704 gallons from deep wells in the chalk. The quantity actually drawn from the Thames was somewhat greater than that stated above, and from the Lea somewhat less, as during the summer months the East London Company have exercised their powers to draw 10,000,000 gallons daily from the Thames at Sunbury.

The samples of water employed for analysis were in all cases taken directly from the mains at places recommended by the respective Companies themselves. Each sample of water has been submitted to the ordinary process of chemical analysis, and in addition the temperature of the waters as they issued from the mains, as well as their appearance in a two-foot tube, has been recorded; whilst in all cases in which the samples were found to be more or less turbid, the suspended matter, which was deposited on standing, was examined under the microscope. The results of these examinations are recorded in the accompanying tables A. to L.

Table A. contains the temperature of each sample at the time of collection from the main. From this table it is seen that the average temperature of all the river waters is practically identical, and that this average differs but slightly from the mean temperature of the deep-well water of the Kent Company. On the other hand it will be observed that the river waters are subject to great fluctuations in temperature according to the season of the year, whilst the temperature of the deep-well water remains almost constant throughout, thus:—

The Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies exhibited variations in temperature from 2°·8 C. (37°·0 Fahr.) in January to 21°·4 C. (70°·5 Fahr.) in July.

The Lea water as supplied by the New River and East London Companies varied in temperature from 3°·4 C. (38°·1 Fahr.) in January to 20°·5 C. (69° Fahr.) in July.

The deep-well water distributed by the Kent Company had a temperature varying from 12° · 0 C. (53° · 6 Fahr.) in January, February, and November to 14° · 5 C.

(58° · 1 Fahr.) in August.

In consequence of this uniform temperature the deep-well water remains refreshing and palatable in summer, whilst in the winter it diminishes the risk of frozen pipes, and is free from the other inconveniences of water but slightly removed from the freezing point.

In Table B. are recorded the total amount of solid matters contained in 100,000 These solid matters are almost parts by weight of the waters respectively. entirely composed of saline substances, which are of no consequence as regards the fitness of the waters for drinking; but salts of lime and magnesia render the waters hard for washing, and, by producing boiler incrustations, are objectionable when the water is used for steam purposes. These solid matters also always contain a small proportion of organic substances, which, although unobjectionable as regards their absolute amount, must, in the case of the river waters, be necessarily viewed with suspicion, when it is remembered that the rivers Thames and Lea receive, above the intakes of the Companies, more or less animal contamination. whether from sewers, or cesspools, from sewage works, or the drainage from manured land. These animal substances may all of them be at any time accompanied by morbific matter capable of producing zymotic disease, and the subsequent treatment of the water, although it greatly diminishes the risk, does not ensure the entire removal of such matters should they be present.

The largest proportion of total solid matters was present in the deep-well water supplied by the Kent Company and by the Tottenham Local Board of Health, whilst the water distributed by the Colne Valley Company contained but little

more than one-third of that in the other two deep-well supplies.

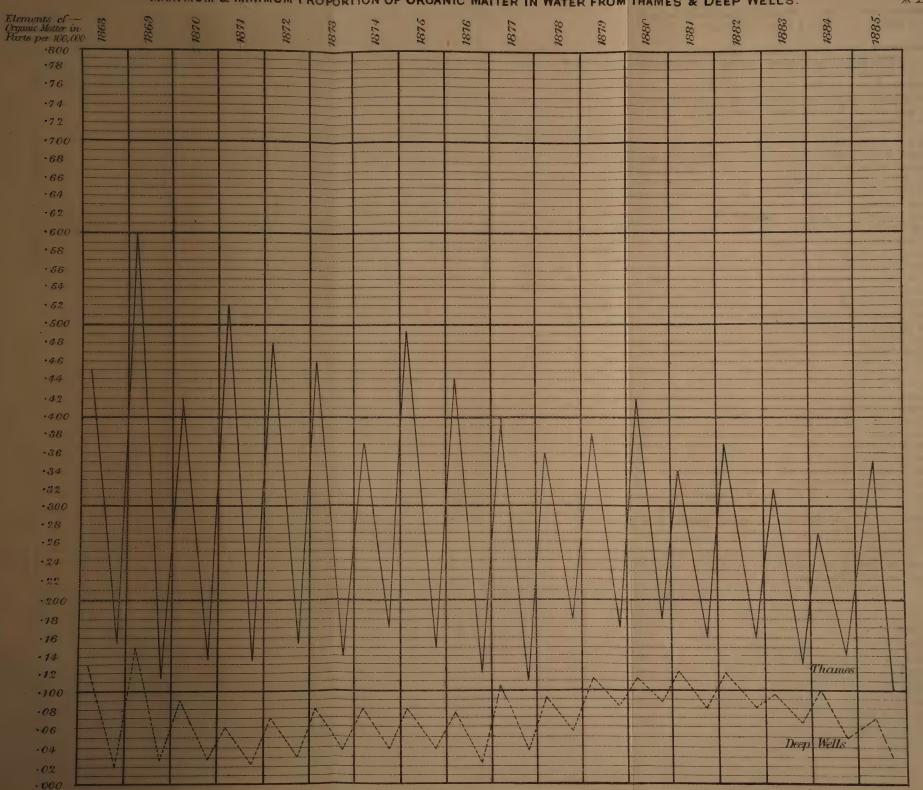

In Tables C. and D. the results of the determinations of organic carbon and nitrogen by combustion are recorded, and by means of these figures we are able to compare the relative proportions of organic matter present in the various waters. These tables show that during the greater part of the year, from March to October inclusive, the proportion of organic matter in the river waters was unusually small, resembling in this respect the exceptional features exhibited in the previous year. During the winter months, however, both in the beginning and at the close of the year, the proportion of organic matter in the river waters rose very considerably, so that the average proportion for the year was somewhat greater than that for 1884. The proportion of organic matter in the deep-well waters was invariably less than in any of the river waters, excepting the New River Company's supply, which during the greater part of the year was, as regards freedom from organic matter, surpassed only by the best of the deep-well waters.

Taking the mean proportion of organic impurity contained in the Thames water delivered in 1868 as 1,000, I find that in the subsequent years, 1885 included, the following proportions were present:—

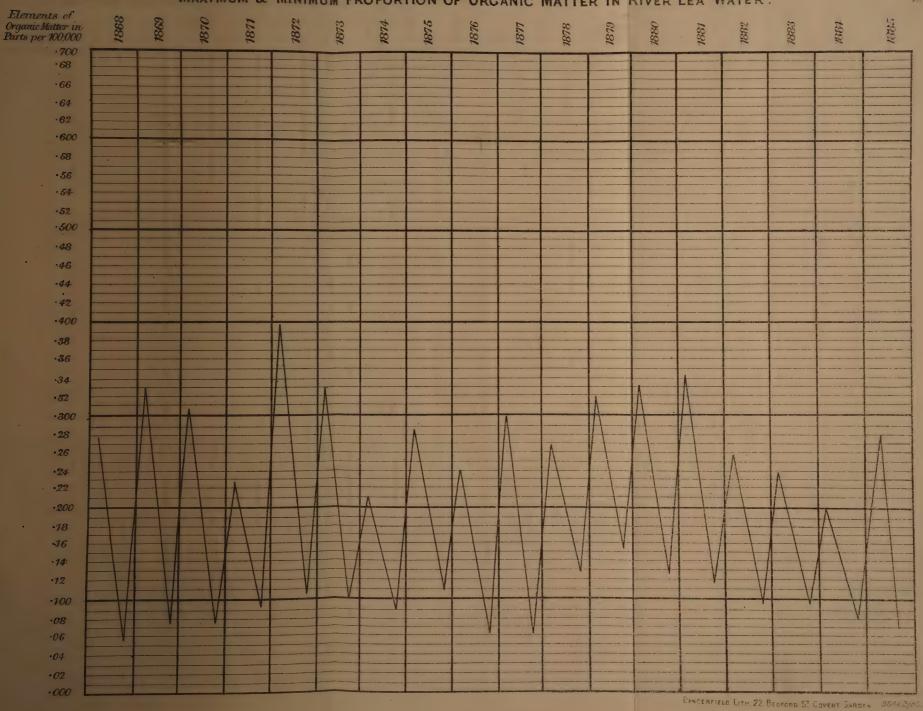

| Year. | | Proportion of organic impur present in Thames water a delivered in London. |
|--------|-----------|--|
| 1868 - | | - 1,000 |
| 1869 - | | 1,016 |
| 1870 - | 1 - | 795 |
| 1871 - | | 928 |
| 1872 - | | - 1,243 |
| 1873 - | 7 Table 1 | 917 |
| 1874 - | | 933 |
| 1875 - | | 1,030 |

rity

DANGERFIELD, LITH. 22, BEDFORD ST COVENT GARDEN. 9541 3/85

MAXIMUM & MINIMUM PROPORTION OF ORGANIC MATTER IN RIVER LEA WATER.

nnic impurity water London.

| Year. | | | | | | 1 | Proportio present deliv | n of organic impurity in Thames water as vered in London. |
|-------|---|------------------|---|----|---|---|-------------------------------|---|
| 1876 | - | | | - | - | - | - | 903 |
| 1877 | | | | | - | - | | 907 |
| 1878 | - | | | 64 | - | - | | 1,056 |
| 1879 | | - | - | | - | - | - | 1,165 |
| 1880 | | , - 1 | | • | - | - | | 1,254 |
| 1881 | | -) | • | - | | - | | 993 |
| 1882 | | - | | | | - | | 1,033 |
| 1883 | | | | - | - | - | | 850 |
| 1884 | | - | - | | • | - | - | 723 |
| 1885 | | | - | | - | ~ | - " | 839 |

These figures show that the average quality of the Thames water supplied to London, as measured by the proportion of organic matter, has, during the past three years (1883–1885), been superior to that supplied in any previous year, excepting 1870, since these examinations were commenced.

In the case of the water drawn from the river Lea, that supplied by the New River Company invariably contained less organic matter than that delivered by the East London Company, which was only rarely superior to the better classes of Thames water.

Taking, as before, the mean proportion of organic impurity in the Thames water supplied to London in 1868 as 1,000, I find in that and the succeeding years, 1885 included, the following proportions in the Lea water delivered by the New River and East London Companies:—

| Year. | | | | | | | | | | | | | | | pre | tion of orga sent in Lea divered in 1 |
|-------|----|---|----|-----|--------------|----|-----|------|---|-------|-------|---|-------|-----|------------------|---|

| 1877 | | | | | • | | | * | | | • | | | • | - " | 596 |
| 1878 | ** | | | - | | | 6- | | | - | | | - | | • | 747 |
| 1879 | | - | | | w , | | | Cla | | | . 648 | | | - | - | 947 |
| 1880 | | | | | | - | | | ~ | | | - | | | 4 | 1,013 |
| 1881 | | - | | | - | | | - | | | - | | | | - | 765 |
| 1882 | | | im | | | | | | - | | | ~ | | | | 711 |
| 1883 | - | | | 140 | | | - | | | ** | | | - | | | 620 |
| 1884 | | | - | | | 60 | | | - | | | | - | | | 500 |
| 1885 | | | | ** | | | - | | | ~ | | | | - ; | , - . | 603 |
| | | | | | | | | | | | | | | | | |

Thus in the case of the Lea, also, the average quality of the water supplied during the past three years has exhibited a marked improvement upon that delivered during the years which immediately preceded this period.

The organic matter present in the deep-well water supplied to London, when compared with the same standard, was:—

| Year. | | |
|---|---|-----|
| 1868 | - | 254 |
| 1869 | - | 312 |
| 1870 | - | 246 |
| 1871 | | 150 |
| 1872 | • | 221 |
| 1873 | - | 250 |
| 1874 - 1/20 - 1/2 | - | 287 |
| 1875 | - | 250 |
| 1876 | - | 246 |
| 1877 | - | 243 |
| 1878 | - | 323 |
| 1879 | - | 387 |
| 1880 | - | 393 |
| 1881 - The second of the secon | - | 405 |
| 1882 - | - | 409 |
| 1883 | - | 321 |
| 1884 | - | 264 |
| 1885 | - | 200 |

Thus the average proportion of organic matter in the deep-well waters was less than one-fourth of that present in the Thames, and barely more than one-third of that in the Lea water. The superiority of the deep-well waters, however, becomes even still more apparent when it is remembered that these waters have undergone a most exhaustive process of natural filtration through porous strata, whilst the river waters are subjected to filtration through only a few feet of sand.

With regard to the water supplied by the Tottenham Local Board of Health, it must be mentioned that, although the samples submitted to analysis are exclusively derived from their deep well, the water actually delivered to the district is not wholly obtained from this source, but is sometimes, I believe, more or less supplemented from the mains of the East London Company.

Table E. exhibits the proportional amount of organic elements (organic carbon and organic nitrogen) in each of the waters, the average amount of these elements contained in the Kent Company's water during the nine years ending December 1876 being taken as unity. This Table shows that the maximum, minimum, and average proportions of organic matter, as measured by this standard, present in the several waters, during 1885, were:—

| Sources. | Maximum. Minimum. Average. |
|---|--|
| $\begin{array}{cccccccccccccccccccccccccccccccccccc$ | - 0.8 0.2 0.5 - 1.4 0.4 0.8 - 1.6 0.6 1.1 |
| $\begin{array}{cccc} {\bf River} & {\bf Lea} & & {\bf -} \left\{ \begin{array}{ccc} {\bf New} & {\bf River} & {\bf -} \\ {\bf East} & {\bf London} & {\bf -} \end{array} \right. \end{array}$ | - 3·9 0·7 1·8 - 5·6 1·7 3·2 |
| River Thames - Chelsea - West Middlesex Southwark - Grand Junction Lambeth - | $\begin{array}{cccccccccccccccccccccccccccccccccccc$ |

These figures afford a general survey of the quality of the various waters, as regards organic matter, throughout the year. Thus, of the water derived from deep wells, it is seen that the supply of the Kent Company was the best, and of the river waters, the New River Company's supply stands first and is far superior

to any of the others. The greatest variation is exhibited by the water of the Grand Junction Company, which, of the Thames supplies, contained both the smallest and the largest proportions of organic matter, the average proportion, however, being only equalled by that of the Southwark Company.

These two Companies are still provided with very inadequate storage capacity for unfiltered water, but having now constructed works for the collection of water from the gravel beds, they are less dependent upon the river itself when the latter is in a flooded condition. These periodical floods to which the rivers Thames and Lea are exposed constitute the greatest difficulty with which the Companies drawing from these sources have to contend, more especially during the winter months. In order to render themselves more independent of the river water when in its worst condition, several of the Companies have, from time to time, increased their storage capacity, and this improvement has had avery beneficial effect upon the average quality of the water which they supply, as is seen from the following table, which shows the maximum amount of organic pollution in the waters supplied from the Thames and Lea during the years 1868 to 1885 inclusive, the average of the samples from each source in the month of greatest pollution being taken for comparison:—

MAXIMUM AMOUNT OF ORGANIC POLLUTION.

| | THA | MES. | | LE | Α. |
|-------|--|---|-------|--|---|
| Year. | Elements of organic matter in parts per 100,000. | Months in which maximum pollution occurred. | Year. | Elements of organic matter in parts per 100,000. | Months in which maximum pollution occurred. |
| 1868 | •45 | January. | 1868 | •27 | February. |
| 1869 | •60 | February. | 1869 | •33 | February. |
| 1870 | •42 | January. | 1870 | •30 | January. |
| 1871 | •52 | October. | 1871 | •22 | February. |
| 1872 | •48 | January & December. | 1872 | •39 | December. |
| 1873 | •46 | January. | 1873 | *33 | January. |
| 1874 | •37 | March. | 1874 | •21 | March. |
| 1875 | *49 | November. | 1875 | •28 | November. |
| 1876 | •44 | December. | 1876 | •24 | March. |
| 1877 | • • 40 | January. | 1877 | •30 | January. |
| 1878 | •36 | December. | 1878 | • 26 | June. |
| 1879 | •38 | February. | 1879 | •33 | July. |
| 1880 | •42 | October. | 1880 | *33 | February. |
| 1881 | •34 | February. | 1881 | •34 | February. |
| 1882 | •37 | November. | 1882 | *26 | December. |
| 1883 | •32 | January. | 1883 | •24 | December. |
| 1884 | . •27 | February. | 1884 | •20 | March. |
| 1885 | *35 | November. | 1885 | •28 | December. |

It thus appears that the maximum amount of organic matter found in the Thames supplies was greater than that in the two previous years, owing to the prolonged floods which prevailed during the month of November.

The general improvement in this respect, however, is strikingly exhibited by the table, and is further illustrated by the accompanying diagrams (*A. & *B.), in which the maximum and minimum proportions of organic matter annually present in each of the three classes of water since 1868 are represented by curves.

Tables F. and G. require no comment.

In Table H. is recorded the total amount of combined nitrogen present in each of the waters. This amount, after making a small correction for the average quantity of combined nitrogen in rain-water, constitutes the whole evidence exhibited by the various waters of the nitrogenous organic substances which they have in the past received as well as of those which they still retained at the time when the analyses were made. In river and other surface waters the quantity of this total combined nitrogen undergoes considerable reduction during the summer months in consequence of the vegetable life then active in these waters, and on this account it is only in the winter months that the amount found can be regarded as in any way a gauge of the nitrogenous matters which have gained access to the water. During the months of January, February, March, October, November, and December the average proportion of total combined nitrogen in 100,000 parts was:—

| Year. | Thames. | Lea. | Deep-Wells. | 1 . |

This progressive reduction which has thus taken place in the amount of combined nitrogen found in the Thames supplies is, in all probability, chiefly due to the longer period of storage to which the water has, of late years, generally been subjected before distribution, for during very prolonged storage in natural lakes the inorganic combined nitrogen almost entirely disappears.

The deep-well water of the Kent and Colne Valley Companies and of the Tottenham Local Board of Health is not exposed to the influences of either vegetable or animal life, and the average proportion of total combined nitrogen given above has, therefore, been taken on the entire year.

In Table I. the proportion of chlorine present in each of the waters is given. From these figures it is evident that no brackish or tidal water has gained access to the companies' supplies.

Table K. records the hardness of the various waters; by hardness is to be understood the proportion of carbonate of lime, or its equivalent of soap-destroying substances, present in 100,000 parts of water. The variations in this respect during the past 5 years for the various classes of water are shown in the following table:—

| Year. | Thames. | Lea. | Kent. | Colne Valley. | Tottenham. |
|-------|---------------|---------|-------|---------------|------------|
| 1881 | 19°·8 | 20° · 8 | 28°·3 | 6°·2 | 24°·1 |
| 1882 | 20°·7 | 21° · 1 | 28°·5 | 5°·5 | 25°·4 |
| 1883 | 19°·9 | 20° · 6 | 28°·0 | 7°·1 | 22°·5 |
| 1884 | 19°•4 | 20°·1 | 28°•6 | 5°•2 | 19°•7 |
| 1885 | 18°• 7 | 20°·0 | 27°•9 | 4°•8 | 20°•4 |

The hardness of water, within the limits exhibited above, is of no material importance when the water is used for drinking, but in the laundry, for the production of steam, and for most manufacturing purposes, a soft water like that of the Colne Valley Company possesses great advantages over a hard one. In all operations in which soap is used as a detergent it is absolutely necessary to have soft water, and if the water be not already soft it must be rendered so before the soap can exert its cleansing properties. This preliminary softening is often

accomplished by means of carbonate of soda so as to avoid the still greater cost which softening by soap entails. On the large scale many waters can be softened by means of lime (Clark's process) for about one-eightieth part of the cost of the soap required for the purpose. Of the water supplied to London, only that furnished by the Colne Valley Company is well fitted for washing and the other purposes specified above. 'The water of this Company is naturally hard like that of the Kent Company, but its hardness is, before delivery, reduced by means of Clark's process to less than one fifth of that present in the water of the Kent Company. The hardness of the river waters could be similarly reduced by this process.

In Table L., lastly, the averages for the past year, of each determination referred to above are collected, so that by its means a general view can be obtained of the quality of the water supplied by each Company throughout the year.

The results of my monthly observations respecting the efficiency of the filtration to which the water drawn from the Thames and Lea had been subjected before distribution are summarized in the following Table, and, by way of comparison, the results of my first observations in 1868 are also recorded:—

| COMPANIES OR LOCAL AUTHORITIES. | Numk occasion clear transp | and | occasio | ber of ns when turbid. | occasion | ber of ns when bid. | | per of as when urbid. |
|---|-------------------------------------|---|--------------------------------|------------------------------|--------------------------------|---------------------------|--------------------------------|--------------------------------|
| THAMES. Chelsea | 1868. 7 12 1 9 6 | 1885. 12 12 12 12 11 12 | 1868. 2 0 5 2 1 | 1885. 0 0 0 1 | 1868. 1 0 4 1 2 | 1885. 0 0 0 0 | 1868. 2 0 2 0 3 | 1885. 0 0 0 0 0 |
| Lea. New River East London DEEP WELLS. Kent Colne Valley Tottenham Local Board of Health | 10 3 8 - | 12 12 12 11 12 | 2 8 3 - | 0 0 | 1 - | 0 0 0 1 | 0 0 | 0 0 0 0 |

It will thus be seen that of all the samples of river water examined throughout the year, only one was otherwise than clear and bright. The contrast between this result and the condition of filtration in 1868 is sufficiently apparent from the Table, but even as compared with the preceding year, 1884, the results obtained for the past year indicate a very marked improvement, for out of the same number of samples examined in 1884 as many as eight were slightly turbid, whilst last year only one sample exhibited any turbidity. This more uniform freedom from turbidity is of the highest importance as indicating the greater care which is now exercised by the Companies, firstly, in abstracting the water from the rivers under the most favourable conditions, and, secondly, in submitting it when so abstracted to a more efficient system of filtration before delivery.

The turbidity found in one of the samples of the Colne Valley Company's water was due to the presence of chalk occasioned by the boring operations which were at the time going on in connection with their well. Otherwise the deep-well water furnished both by this and the Kent Company, and by the Tottenham Local Board of Health, is uniformly clear and bright, and requires, therefore, no artificial filtration.

The sediment deposited by the turbid samples on standing was, as usual, submitted to microscopic examination, without, however, any moving organisms being dis-

covered in the sediment deposited. In the following Table the results of microscopic examinations, made during the past 17 years, are collected:—

NUMBER of OCCASIONS when MOVING ORGANISMS were found.

In a still more striking manner is the improvement effected in the river waters by filtration revealed by the determinations of the relative number of micro-organic spores or germs present in a given volume of the raw and filtered waters. These determinations have been made by my son, Dr. Percy Frankland, during the past year, and the results are recorded in his report to the Local Government Board. They show that whilst the unfiltered Thames water exhibited by gelatine cultivation, on an average, 2,219 germs per cubic centimetre, the filtered water contained only 38, which corresponds to a reduction of 98°3 per cent.

I am, &c."
E. FRANKLAND.

The Registrar General, &c., &c. Somerset House, W.C.

Note.—The numbers in these tables may be converted into grains per imperial gallon, by multiplying them by 7, and moving the decimal point one place to the left.

FIRES IN LONDON DURING THE YEAR 1885.

Captain Eyre M. Shaw, Chief Officer of the Metropolitan Fire Brigade, reported to the Metropolitan Board of Works that the number of fires attended during 1885 was 2270, showing a decrease of 19 from the number in the preceding year, but being 441 above the average in the ten years 1875–84. The lives of 201 persons were seriously endangered, and 47 of these were lost. The numbers of lives lost by fires in London in the three preceding years were 39, 39, and 42 respectively.

The establishment of the Metropolitan Fire Brigade at the end of the year was distributed at 55 engine, 26 hose cart, 127 escape, and 4 floating stations. The number of fire engines at these stations was 170, showing a decrease of 1 from the number in the previous year; 4 were floating steam engines, 42 land steam engines, and 124 manual engines. The strength of the brigade was 589 of all ranks, including the chief officer and the superintendents, and corresponded with the strength in the previous year. The cases of injury occurring in the brigade during the year were 117, against 121, 92, and 142 in the three previous years.

Number of Fires and of False Alarms attended during the Twelve Years 1874-85, and in each Month of 1885.
